

Client Check in

Johann -> Kayne Feedback

- Data preparation (cleaning, handling outliers, rkm handling) was done well.
- Encounter-level table + justification on your choices were well supported.
- Clear justification for pursuing Option C as well as documenting limitations for Options A and B.
- Phase 2 supervised classification plan makes sense after this EDA.
- Only suggestion for the next part + presentation is to make the connection between your EDA results (the high-prio results) and the final recommendation for where to focus monitoring efforts a bit clearer. All while making sure to continue stating that the dataset only shows where the fish were captured, not how much monitoring effort was used in each location.

Kayne -> Johann Feedback

Phase 1

- I agree that Option C is the strongest option based on the current data.
- For Option A, I would avoid saying that more advertising would improve reviews because the dataset does not include advertising or player acquisition data.
- For Option B, I would also be careful about connecting better review sentiment after updates to better communication. The dataset does not directly measure communication.
- So I think it is fine to say that Options A and B cannot be strongly tested with the available data, while Option C can be directly supported.

Dataset size

- I noticed that you are using the larger dataset instead of the smaller 2,400-review sample from my proposal.
- I am okay with this if you explain why you chose the larger dataset.
- If Phase 2 becomes too computationally heavy, I am also okay with using a reproducible sample of the negative reviews.

Playtime analysis

- I think this is one of the strongest parts of the EDA. It might be useful to create playtime groups and compare the percentage of negative reviews in each group.
- I would describe Hours Played as experience with Cyberpunk 2077, rather than general reviewer experience.

Received for Free

- I would not describe this as purchase status and I also would not use it to conclude that price is not an important issue.
- I think the safer conclusion is that receiving the game for free does not appear to have a strong relationship with recommendation outcome.

Review timeline and updates

- I like the timeline analysis. I think the percentage of negative reviews is more useful than only showing the raw number of negative reviews.
- It could also be useful to compare recommendation rates across major update categories such as Release, Patch 1.6, and Patch 2.0.

Review length and helpful votes

- The finding that negative reviews are longer is useful because it supports doing text analysis.
- Helpful votes seem very skewed, so I would consider using the median or the percentage of reviews with at least one helpful vote instead of relying mainly on the average.

NLP and Phase 2

- I like the word counts, bigrams, and trigrams as an early check that repeated complaint topics exist.
- The final clustering should ideally produce around four to eight clear complaint themes.
- Each theme should include useful keywords and some representative reviews so the cluster is easy to understand.

Final stakeholder recommendation

- After creating the clusters, I would like you to compare their size, player playtime, helpful votes, review length, and update period. But, again, it's totally up to you if you only focus on certain aspects!
- The final result should identify the top two or three complaint themes that Kosima Production should prioritize.
